An embodiment in accordance with the present invention provides a robot structure that includes an MRI-safe pneumatic stepper motor and optical encoding technologies. The present invention includes a needle guide and a needle depth limiter. The needle for biopsy is inserted through the needle guide and the depth of inserting is limited by the needle depth limiter. The robot is configured to control this procedure. The robot structure is adapted for biopsy, a novel way of setting the depth of needle insertion, image-to-robot registration. The system includes control for the robot.

CROSS-REFERENCE TO RELATED APPLICATIONS

This application is a 35 U.S.C. § 371 U.S. national entry of International Application PCT/US2017/033991, having an international filing date of May 23, 2017, which claims the benefit of U.S. Provisional Application No. 62/340,006, filed May 23, 2016, the content of each of the aforementioned applications is herein incorporated by reference in their entirety.

GOVERNMENT SUPPORT

The present invention was made with government support under RC1EBO10936 awarded by the National Institutes of Health. The government has certain rights in the present invention.

FIELD OF THE INVENTION

The present invention relates generally to medical devices. More particularly, the present invention relates to a needle-guide robot with a preset depth of insertion.

BACKGROUND OF THE INVENTION

Needle-guidance for diagnostic and therapy image-guided interventions can be accomplished with indirect or direct guidance methods, both having potential advantages. Direct methods use the imager at the time of the procedure. These are potentially more accurate for targeting, but special devices are needed to help the physician perform the intervention. If used in conjunction with magnetic resonance imaging (MRI) equipment, devices have very stringent compatibility requirements. Devices for the MR have been initially classified as MRI Compatible or Incompatible, as early as 1993. While the name stuck, there was no formal definition and the classification was insufficiently descriptive. Instead, standards such as the American Society for Testing and Materials (ASTM) classify (ASTM F2503) devices for the MR environment (Table 1), and set a series of tests that these should meet (ASTM F2052, F2213, F2182, F2119) Most importantly, for clinical use in the United States compliance to these standards is mandated by the Food and Drug Administration (FDA).

<table>
<thead>
<tr>
<th>ASTM F2503-13 Classification and Marking for the MR Environment</th>
</tr>
</thead>
<tbody>
<tr>
<td>MRI-Safe</td>
</tr>
<tr>
<td>MRI-Conditional</td>
</tr>
</tbody>
</table>

The standard points out rationally that devices made exclusively of nonconductive, nonmetallic, and nonmagnetic materials pose no known hazards in the MR environment. The standard also sets the regulatory basis for the determination of MRI safety based on this underlying scientific rationale.

Since testing a device in all MR environments is impossible, the standard impractically excludes devices that use electricity from the MR Safe category. Several research teams have demonstrated that electrical devices (MR Conditional) can be safely used in the MRI. Since one would not have to use a device in all MR environments, proper tests in the MR equipment of choice could make the MR Conditional device a useful clinical instrument for the specific procedure. Nevertheless, devices that meet the MR Safe standard require less testing for a wider application range. Therefore, the preferential choice when developing a device for the MR is MR Safe, because this facilitates clinical translation under the regulatory protocols and a broader dissemination.

The development of devices that may operate accurately and safely in the MR environment without interfering with the functionality of the imager has been a very challenging engineering task. As such, initial devices developed for direct MRI guided procedures were manually operated. These have the merit of bringing the procedure first to clinical trials. Following research pursued the development of remotely controlled and robotic devices to facilitate the procedure. These required additional developments related to sensing and actuation, since most of the components traditionally used in robotics are MR Unsafe (e.g., electromagnet motors). Technical developments of over a decade of research in the field have enabled building several MR Conditional and MR Safe robots. Yet few have reached the clinical trial stage.

Therefore, it would be advantageous to provide a needle-guide robot with a preset depth of insertion.

SUMMARY OF THE INVENTION

The foregoing needs are met, to a great extent, by the present invention, wherein in one aspect a method of needle insertion includes inserting a needle manually. The method includes inserting the needle through a needle-guide. The method includes limiting a direction of insertion with the needle-guide. Additionally, the method includes limiting a depth of insertion with a limiter of the needle-guide configured to preset the depth of insertion.

In accordance with an aspect of the present invention, the method includes stopping the needle assembly when it comes into contact with a stopper surface of the depth limiter at a location that corresponds to the preset depth of needle insertion. The method includes using a sterile bag to maintain sterility of the robot. The method also includes using a motor configured to set a position of the depth limiter...
relative to the needle-guide. Additionally, the method includes using a stepper motor.

In accordance with an aspect of the present invention, a device for needle insertion includes a needle driver device. The device includes a needle-guide. The device also includes a depth limiter.

In accordance with another aspect of the present invention, the needle-guide is a sterile and biocompatible component. A surface of the needle assembly comes into contact with a stopper surface of the depth limiter at a location that corresponds to a preset depth of needle insertion. A surface of the needle and limiter come in contact through a bag. A motor is configured to set a position of the depth limiter relative to the needle-guide. The motor is a pneumatic stepper motor. A screw mechanism is configured to set the position of the limiter. The position of the depth limiter is configured to be adjusted so that the location presents the desired depth of needle insertion. The device includes image registration markers. The device is configured to be MR-safe. A robot is included that manipulates the needle driver device. The robot is instrumented with registration markers for image-guided medical applications. The MR-Safe and MR-Unsafe components are configured to be separated. The device can include a sterile (or clean) bag, such that the entire robot is sterile.

**BRIEF DESCRIPTION OF THE DRAWINGS**

The accompanying drawings provide visual representations, which will be used to more fully describe the representative embodiments disclosed herein and can be used by those skilled in the art to better understand them and their inherent advantages. In these drawings, like reference numerals identify corresponding elements and:

FIG. 1 illustrates a system schematic, according to an embodiment of the present invention.

FIGS. 2A-2C illustrate views of the robot and needle driver, according to an embodiment of the present invention.

FIG. 3 illustrates a schematic diagram of a robot controller, according to an embodiment of the present invention.

**DETAILED DESCRIPTION**

The presently disclosed subject matter now will be described more fully hereinafter with reference to the accompanying Drawings, in which some, but not all embodiments of the inventions are shown. Like numbers refer to like elements throughout. The presently disclosed subject matter may be embodied in many different forms and should not be construed as limited to the embodiments set forth herein; rather, these embodiments are provided so that this disclosure will satisfy applicable legal requirements. Indeed, many modifications and other embodiments of the presently disclosed subject matter set forth herein will come to mind to one skilled in the art to which the presently disclosed subject matter pertains having the benefit of the teachings presented in the foregoing descriptions and the associated Drawings. Therefore, it is to be understood that the presently disclosed subject matter is not to be limited to the specific embodiments disclosed and that modifications and other embodiments are intended to be included within the scope of the appended claims.

An embodiment in accordance with the present invention provides a robot structure that includes an MRI-Safe pneumatic step motor and optical encoding technologies. The robot structure was initially built for seed brachytherapy, as a showcase of technology that can operate fully automatically with no human intervention in the MRI scanner. Preclinically this was very successful, but brachytherapy and full robotic operation were not enablers for immediate clinical translation. Therefore, the present invention was adapted for a biopsy procedure and scaled down the system to manual needle insertion. The robot structure was adapted for biopsy, a novel way of setting the depth of needle insertion, image-to-robot registration.

The biopsy device is a 5-DoF robotically driven needle-guide and a 1-DoF depth of needle insertion limiter. The system 10 includes the robot 12, its controller 14, and a computing device 16 for image registration and navigation, as shown in FIG. 1. The robot 12 goes in the MRI scanner room 18 (ACR Zone IV) separated by a waveguide 20 and mounts on the MRI table. FIG. 1 illustrates a system schematic, according to an embodiment of the present invention. As illustrated in FIG. 1, the system includes the robot 12 for controlling the needle 22, needle guide 24, and depth limiter 26 within the MRI scanner room 18. The MR console 28, image registration and navigation module 30, and robot controller 14 sit outside the MR scanner room 18 and allow for control of the MR scanner 32 and robot 12 within the MR scanner room 18. The robot controller can be specifically designed for the present invention, in order to provide control of the robot. The robot controller 14, MR console 28, and image registration and navigation module 30 can be incorporated into one computing device or separate computing devices and controls. If separate, the devices can be networked together either by wire or wirelessly.

Further with respect to FIG. 1, a bundle of hoses 34 including pneumatic circuits and optic fibers connect the robot 12 to its robot controller 14 located outside the MRI room 18 (ACR Zone III). The hoses 34 are passed through a standard access waveguide 20 and attach to the robot 12 with a custom-built optic and pneumatic connector. A registration marker is built within the base of the needle-guide. MRI images are acquired and passed in DICOM (Digital Imaging and Communications in Medicine) format to the robot controller over the network.

If they are not incorporated into one computing device, the robot controller 14 can be located physically next to the MM console. Images showing the registration marker are used for robot-to-image registration. Target biopsy locations are selected in the MRI, and the points are mapped to robot-space coordinates based on the registration. The robot controller 14 further maps the robot-space to joint-space coordinates using the inverse kinematics of the robot 12, and controls the actuators in closed-loop position feedback. This aligns the needle-guide 24 on target for biopsy, locks the location of the needle-guide 24 in place (non-back-drivable actuators), and sets the position of the depth limiter 26. The needle 22 is then inserted manually through the needle-guide 24, up to the depth limiter 26. The biopsy is sampled manually, as usual.

FIGS. 2A-2C illustrate views of the robot and needle driver, according to an embodiment of the present invention. The robot 100 includes the 5-DoF parallel link structure 102 of the robot 100 and a 1-DoF needle-driver 104 newly developed for biopsy, as shown in FIG. 2A. The 5-DoF parallel link structure 102 positions (3-DoF: X, Y, Z axes) and orients (2-DoF: about X, Y axes) the 1-DoF needle-driver assembly 104 with 5 linear actuators, implemented with screw drivers from rotary pneumatic stepper motors (rotary nut, sliding screw). The structure attaches with suction cups 106 to an adapter plate mounted on the MRI table. The height of the robot 100 over the table can be
adjusted by the length of the suction cup mounts 108. A needle guide 110 is positioned at a distal end of the 1-DoF needle driver.

The 1-DoF needle-driver assembly and its schematic are presented in FIGS. 2B and 2C, respectively, according to an embodiment of the present invention. The needle-guide 110 is attached to the base of the driver (the platform driven by the 5-DoF parallel link), as illustrated in FIG. 2A. A slider block 112 having a stopper/limiter surface 116 is positioned by a 6th pneumatic stepper motor 114 through a screw driver (rotary screw, sliding nut). The needle 118 is passed through the needle-guide 110 until the needle handle 120 touches the stopper/limiter surface of the slider block 112, thus limiting the depth of insertion as needed to reach the target, based on the images. A registration marker 122 is included to allow for visualization of the needle 116.

The 1-DoF needle is covered with a sterile bag 124 and the only sterilized component is the needle-guide 110 (and of course the single-use needle 118). The placement of the sterile bag 124 about the driver is illustrated in FIG. 2C, which shows how the components were designed so that the needle-guide 110 attaches over the sterile bag 124 (with 2 screws) and the needle handle 120 touches the limiter through the bag. The robot is electricity-free, uses air pressure for actuation, light for the position sensors, and is entirely made of nonconductive, nonmetallic, and nonmagnetic materials. Moreover, the needle-guide, which comes in direct contact with the patient, is built of certified biocompatible material (ISO-10993).

Two types of needles can be used with the present invention, both manufactured by Invivo, Pewaukee, Wis.: 9806-032-02861 (11528), 18G×150 mm Semi-Automatic Biopsy Gun and 9806-032-05281, 18G×175 mm Fully Automatic Biopsy Gun (shown in FIG. 2B). Alternately, any suitable needle known to or conceivable by one of skill in the art could also be used. Accordingly, different limiters for the needle-driver were used to accommodate their different handles.

FIG. 3 illustrates a schematic diagram of a robot controller, according to an embodiment of the present invention. The robot controller includes a PC running Microsoft Windows 7, a motion control card, electro-pneumatic and electro-optical interfaces, and several safety components, as illustrated in FIG. 3. The motion control card (MCC, MC-8000, PMDI, BC, Canada) presents a digital signal processor (DSP) that is responsible for axis-level coordinated motion control in real-time.

The electro-optical interface converts optical quadrature encoded signals from the pneumatic stepper motors to typical electric signals for the MCC. These are implemented with D10 Expert fiber optic sensors (Banner Engineering Corp., Minneapolis, Minn., USA). Position feedback signals are used for closed-loop stepper control of each pneumatic stepper axis. Each linear actuator axis is also equipped with a limit switch, also implemented with fiber optic sensors. These are used to home the incremental encoders of the motors. The home position of the robot is shown in FIG. 2A, chosen at a central (square) position of the parallel links.

The electro-pneumatic interface includes a driver for the pneumatic stepper motor and pneumatic valves. The driver converts standard step and direction electric signals of the MCC to three electric signals that sequentially actuate three pneumatic direct acting solenoids (NVRF33A-V-5D by SMC Corp., Indianapolis, Ind., USA). In turn, these generate pneumatic commutation waves that power the pneumatic stepper motor.

Safety components include a watchdog, emergency stop buttons, and visual alerts, as shown in the block diagram of the robot controller (FIG. 3). This system design has been developed according to a Risk Hazard Analysis. However, any other implementation of the system design could also be used. The watchdog has a software and a hardware component used to mitigate software errors that are possibly undeterministic. The software watchdog checks the state of several components of the system, disabling power to the pneumatic valves, should a faulty condition occur. It runs on a separate (time critical) thread and signals its continuous operation to the hardware watchdog, which suspends power after 100 ms of software watchdog inactivity.

Visual signs are used to signal the operation state of the robot. Two Emergency Stop buttons, of which one is located on the MRI table next to the patient, disable the system and suspend the pneumatic pressure through a circuit that is separate from the watchdog.

The motion control software includes axis-level motion control and robot kinematics software built in Visual G (Microsoft Corp., Redmond, Wash.). Axis-level control is implemented on the MCC is developed based on libraries of the MCC (MCI-SoftLib, PMDI). Robot kinematics has been derived based on link parameters resulting from the Computer Aided Design (CAD) of the robot.

The depth of needle insertion is also calculated based on the images and referenced in the robot CsSys. The desired depth of needle insertion is calculated by referencing the depth of the needle to the center of the biopsy core slot. For the fully automated biopsy gun, the depth is also offset with the forward-fire distance of the needle. With these, the target biopsy point selected in MRI corresponds to the center of the biopsy sample. As such, in the case of the fully automated biopsy gun, the limiter sets the depth of insertion short of the target, and the target is reached only after firing the needle, as usual.

The present invention demonstrates that accurate direct MRI-guided needle targeting is possible. In the human trials, the robot was capable of 2.97 mm 3D accuracy and 2.55 mm in a plane normal to the needle. For PCA the required accuracy is probably <5 mm, since a clinical significant tumor (0.5 cm³) has a 5 mm radius if spherical. Targeting errors include numerous components which are often cumulative: image geometry errors, registration errors, robot position errors, robot structural deformations under load, and never the less needle deflections. A detailed error component analysis is therefore helpful, and all components that can be minimized/mitigated should. For example, to finally keep the needle within 5 mm of the target: pneumatic stepper motor (37 W) linear step 0.055 mm, a flat parallel link structure, bench tests of motion 0.076±0.035 mm, linear motion in a 7T MRI scanner 0.047±0.053 mm, motion repeatability 0.060 mm, placing seeds in agar models 0.72±0.36 mm and under 3T MRI guidance 1.2 mm (SD 0.4 mm), targeting under 3T MRI in an animal model with needle accuracy of 2.02 mm (range 0.86-3.18 mm) and seed placement accuracy of 2.50 mm (range 1.45-10.54 mm), and registration errors of 0.25 mm (SD 0.31 mm) reported herein.

The robot of the present invention presents a 5-DoF parallel link structure to position and orient a needle-guide and a 1-DoF stopper to limit the depth of manual needle insertion. The limiter feature and its arrangement under the sterile bag is novel and reduces the number of sterile components to the needle-guide alone. In most image-guided robots and all 4 that were used clinically the depth is decided by the operator who typically looks up the marks on
the needle. This is adequate since accurate control of the needle depth for biopsy is not critical. The length of the biopsy slot (typically 17 mm) is forgiving for errors in depth (perhaps within (17–10)/2 = ±3.5 mm). For this most needle targeting studies report the normal plane values alone. With the actuated limiter, the depth is also very accurately controlled, as shown by the small empirical variation between the accuracies in 3D (2.97 mm) and normal plane (2.55 mm). The automation reduces the workload of the operator who manipulates the biopsy needle in a tight space of the MRI scanner gantry and the possibility of errors. Also, the improved accuracy could be helpful for other procedures such as ablations where depth may be critical. The achieved MRI-based targeting accuracy of 2.55 mm of the present invention is outstanding.

The movement and actuation of the present invention can be carried out using a computer, non-transitory computer readable medium, or alternately a computing device or non-transitory computer readable medium incorporated into the robotic device or the imaging device.

A non-transitory computer readable medium is understood to mean any article of manufacture that can be read by a computer. Such a non-transitory computer readable media includes, but is not limited to, magnetic media, such as a floppy disk, flexible disk, hard disk, reel-to-reel tape, cartridge tape, cassette tape or cards, optical media such as CD-ROM, writable compact disc, magneto-optical media in disc, tape or card form, and paper media, such as punched cards and paper tape. The computing device can be a special computer designed specifically for this purpose. The computing device can be unique to the present invention and designed specifically to carry out the method of the present invention. The computing device can also take the form of an operating console computer for the imaging device or the robotic device. The computing console for the imaging device or the robotic device is a non-generic computer specifically designed by the manufacturer. It is not a standard business or personal computer that can be purchased at a local store. Additionally, the console computing device can carry out communications with the scanner through the execution of proprietary custom built software that is designed and written by the manufacturer for the computer hardware to specifically operate the hardware.

The many features and advantages of the invention are apparent from the detailed specification, and thus, it is intended by the appended claims to cover all such features and advantages of the invention which fall within the true spirit and scope of the invention. Further, since numerous modifications and variations will readily occur to those skilled in the art, it is not desired to limit the invention to the exact construction and operation illustrated and described, and accordingly, all suitable modifications and equivalents may be resorted to, falling within the scope of the invention.

What is claimed is:

1. A device for needle insertion comprising:
   a. a needle driver device;
   b. a needle-guide, wherein a direction of insertion of a needle can be preset using the needle guide; and
   c. a depth limiter, wherein a depth of insertion of the needle can be preset using the depth limiter, wherein a body of the needle contacts the depth limiter, and the depth limiter thereby limits the depth of the insertion of the needle, and wherein the needle driver device actuates the needle-guide and the depth limiter.

2. The device of claim 1 wherein the needle-guide is a sterile and biocompatible component.

3. The device of claim 1, wherein the needle body comes into contact with a stopper surface of the depth limiter at a location that corresponds to a preset depth of needle insertion.

4. The device of claim 3, wherein a surface of the needle and limiter come in contact through a bag.

5. The device of claim 1, further comprising a motor configured to set a position of the depth limiter relative to the needle-guide.

6. The device of claim 5, wherein the motor is a pneumatic stepper motor.

7. The device of claim 5, further comprising a screw mechanism configured to set the position of the limiter.

8. The device of claim 1, wherein the position of the depth limiter is configured to be adjusted so that a location presets the desired depth of needle insertion.

9. The device of claim 1, further comprising image registration markers.

10. The device of claim 1, wherein the device is configured to be MRI-safe.

11. The device of claim 1, further comprising a robot that manipulates the needle driver device.

12. The device of claim 11, further comprising the robot being instrumented with registration markers for image-guided medical applications.

13. The device of claim 11, wherein the device is configured to be MRI-safe.

14. The device of claim 11, wherein the MRI-safe and MRI-unsafe components are configured to be separated.

15. The device of claim 11 further comprising a sterile (or clean) bag, such that an entirety of the robot is sterile.

16. A device for needle insertion comprising:
   a. a needle guide;
   b. a needle-guide, wherein a direction of insertion of a needle assembly can be preset using the needle guide; and
   c. a depth limiter, wherein a depth of insertion of the needle can be preset using the depth limiter and wherein the depth limiter includes a stopper surface wherein a body of the needle contacts the depth limiter, and the depth limiter thereby limits the depth of the insertion of the needle and wherein a surface of the needle assembly comes into contact with the stopper surface of the depth limiter at a location that corresponds to a preset depth of needle insertion.
